Regulatory & Support Copilot — Project Proposal

Oct 19, 2026 ·

1. Project Overview

We propose an AI agent system that helps a payments software company handle new banking regulations and customer support tickets faster.

Our case study is **ProgressSoft**, a Jordanian fintech company in Amman. It builds payment and clearing systems, such as cheque clearing and instant payments, for central banks and commercial banks in many countries.

The system is called the **Regulatory & Support Copilot**. It reads documents, finds what changed, and prepares work for the company's staff. A human always makes the final decision.

Note: the problem is based on the type of business ProgressSoft runs, not on internal company data. We will use mock and public data.

2. The Problem

The company spends a lot of expert time on two repeated, manual tasks.

1. **Handling new regulations.** Central banks often publish new rules and new message formats (such as ISO 20022). Staff must read each one, find which product parts and which clients it affects, and write the required changes.
2. **Answering support tickets.** Banks ask questions like "Why was this payment rejected?" An engineer must read logs and settings to find the answer.

Why it happens

Cause	Result
One product, set up differently for each client	Hard to know which clients a new rule affects

Cause	Result
Long regulation documents in several languages	Days of reading and summarizing
Changes mapped to the product by hand	Slow work and human mistakes
Knowledge held by a few senior experts	Delays when they are busy or leave
Tickets need manual log checking	Long waits for banks, engineers pulled from development

3. Objectives and Scope

The goal is to turn days of manual reading and checking into hours, while staff stay in control.

Objectives

- Summarize a new regulation automatically: what changed and when it starts.
- Find which product parts and which clients are affected.
- Draft change requests with acceptance criteria and test cases.
- Diagnose common support tickets and draft a clear reply.

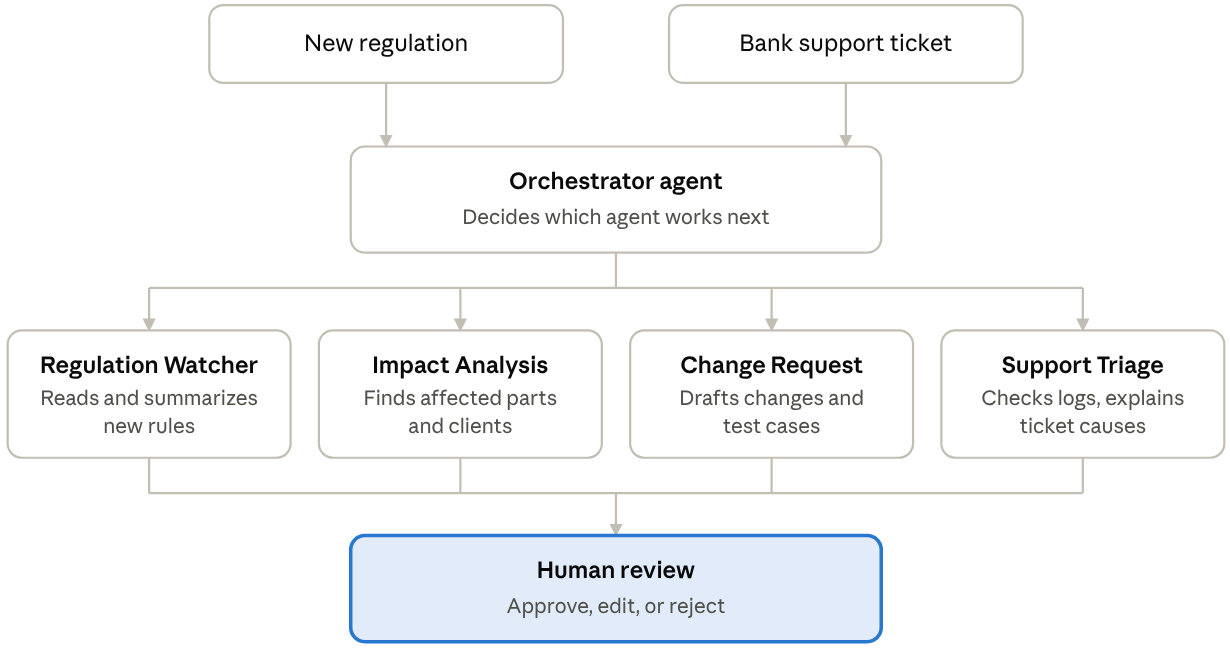

Out of scope

- The system does not change code or client settings by itself.
- The system does not send anything to banks without human approval.
- The system does not process real payments.

4. Proposed Solution

The solution is a team of AI agents. Each agent does one job, and a lead agent (the orchestrator) coordinates them.

Agents prepare the work, a human makes every decision

system design · 1 orchestrator, 4 agents, 1 human review

Regulations go to the first three agents in order. Tickets go to the Support Triage agent. All results stop at a human before anything is used.

5. How It Works

The system runs two main workflows, and each ends with a human review.

Workflow A: a new regulation arrives

1. The regulation document is uploaded.
2. The system summarizes what changed.
3. It lists the affected product parts and clients.
4. It drafts change requests and test cases.
5. A business analyst reviews and approves them.

Workflow B: a bank opens a support ticket

1. The system reads the ticket.
2. It checks the related logs and error codes.
3. It explains the cause in simple words.
4. A support engineer reviews the reply and sends it.

Simple technical explanation

- **Large Language Model (LLM):** the "brain" that reads, understands, and writes text.
- **RAG (Retrieval-Augmented Generation):** the system first searches the company's own documents, then answers from them. This keeps answers based on real facts.
- **Vector database:** stores the documents in a form that allows search by meaning, not only by keywords.
- **Tools:** agents can call simple services, such as a log search, a message format checker, and a ticketing system.
- **Suggested stack:** Python, an agent framework (such as LangGraph or CrewAI), a vector database (such as Chroma or Qdrant), and a simple web page for reviews.

6. Safety, Expected Outcomes, and Plan

Banking data is sensitive, so safety rules are built in from the start.

Safety rules

- A human approves every change request and every reply.
- Agents can read logs and settings but never change them.
- Account numbers and personal data are hidden before the AI sees them.
- Every action is saved in an audit log.

Expected outcomes

- A working prototype of both workflows, using mock data.
- Faster regulation handling and faster ticket replies, measured against manual work.
- Answers that point to the source document they came from.

Project plan

1. Research payment systems and ISO 20022 basics.
2. Prepare mock documents, client settings, logs, and tickets.
3. Build the document search (RAG).
4. Build and test each agent.
5. Connect the agents and add the review page.
6. Test, measure results, and present a final demo.
